ITERATION WITH RECURSION

Generate n random numbers

```scala
import scala.util.Random

def randomNumbers(length: Int): List[Int] =
  if(length <= 0) Nil
  else {
    val number = Random.nextInt(100)
    number :: randomNumbers(length - 1)
  }
```

```scala
randomNumbers(2)
// res0: List[Int] = List(18, 10)
randomNumbers(5)
// res1: List[Int] = List(16, 90, 85, 62, 51)
randomNumbers(-1)
// res2: List[Int] = List()
```

Termination conditions

```scala
import scala.util.Random

def randomNumbers(length: Int): List[Int] =
  if(length == 0) Nil
  else {
    val number = Random.nextInt(100)
    number :: randomNumbers(length - 1)
  }
```

```scala
randomNumbers(2)
// res4: List[Int] = List(64, 29)
```

```scala
randomNumbers(-1)
// error: java.lang.StackOverflowError
```

Termination conditions

```scala
import scala.util.Random

def randomNumbers(length: Int): List[Int] =
  if(length == 0) Nil
  else {
    val number = Random.nextInt(100)
    number :: randomNumbers(length - 1)
  }
```

```scala
randomNumbers(2)
// res6: List[Int] = List(45, 31)
```

```scala
randomNumbers(-1)
// error: java.lang.StackOverflowError
```

Infinite recursion

```scala
def doSomething: String = doSomething
```

```scala
def doSomething: String = {
  while(true) { /* do nothing */ }
  ???
}
```

Generalise with Function0

```scala
def repeat[A](length: Int, action: () => A): List[A] =
  if(length <= 0) Nil
  else {
    val result = action()
    result :: repeat(length - 1, action)
  }
```

Generalise with Function0

```scala
def repeat[A](length: Int, action: () => A): List[A] =
  if(length <= 0) Nil
  else {
    val result = action()
    result :: repeat(length - 1, action)
  }
```

```scala
repeat(5, () => Random.nextInt(100))
// res8: List[Int] = List(68, 27, 53, 76, 28)

repeat(2, () => println("Hello"))
// Hello
// Hello
// res9: List[Unit] = List((), ())
```

Generalise with call-by-name parameter

```scala
def repeat[A](length: Int, action: => A): List[A] =
  if(length <= 0) Nil
  else {
    val result = action
    result :: repeat(length - 1, action)
  }
```

```scala
repeat(5, Random.nextInt(100))
// res11: List[Int] = List(11, 12, 86, 44, 34)

repeat(2, println("Hello"))
// Hello
// Hello
// res12: List[Unit] = List((), ())
```

Generalise with call-by-name parameter

```scala
def repeat[A](length: Int, action: => A): List[A] =
  if(length <= 0) Nil
  else
    action :: repeat(length - 1, action)
```

```scala
repeat(5, Random.nextInt(100))
// res14: List[Int] = List(58, 8, 69, 47, 93)

repeat(2, println("Hello"))
// Hello
// Hello
// res15: List[Unit] = List((), ())
```

Retry

```scala
import scala.util.{Try, Success, Failure}

def retry[A](remainingRetries: Int, action: => A): A =
  Try(action) match {
    case Success(value)     => value
    case Failure(exception) =>
      if(remainingRetries <= 0) throw exception
      else retry(remainingRetries - 1, action)
  }
```

Recursive data structure

- List
- Tree: JSON, file system
- case class Person(name: String, children: List[Person])

Problems with recursions

to understand what is recursion, we need to first understand recursion

```scala
def doSomething: String = doSomething
```

```scala
def doSomething: String = {
  while(true) { /* do nothing */ }
  ???
}
```

Disk Usage

```
sbt new scala/scala-seed.g8
cd scala-seed-project
```

```
diskUsage(".")
```
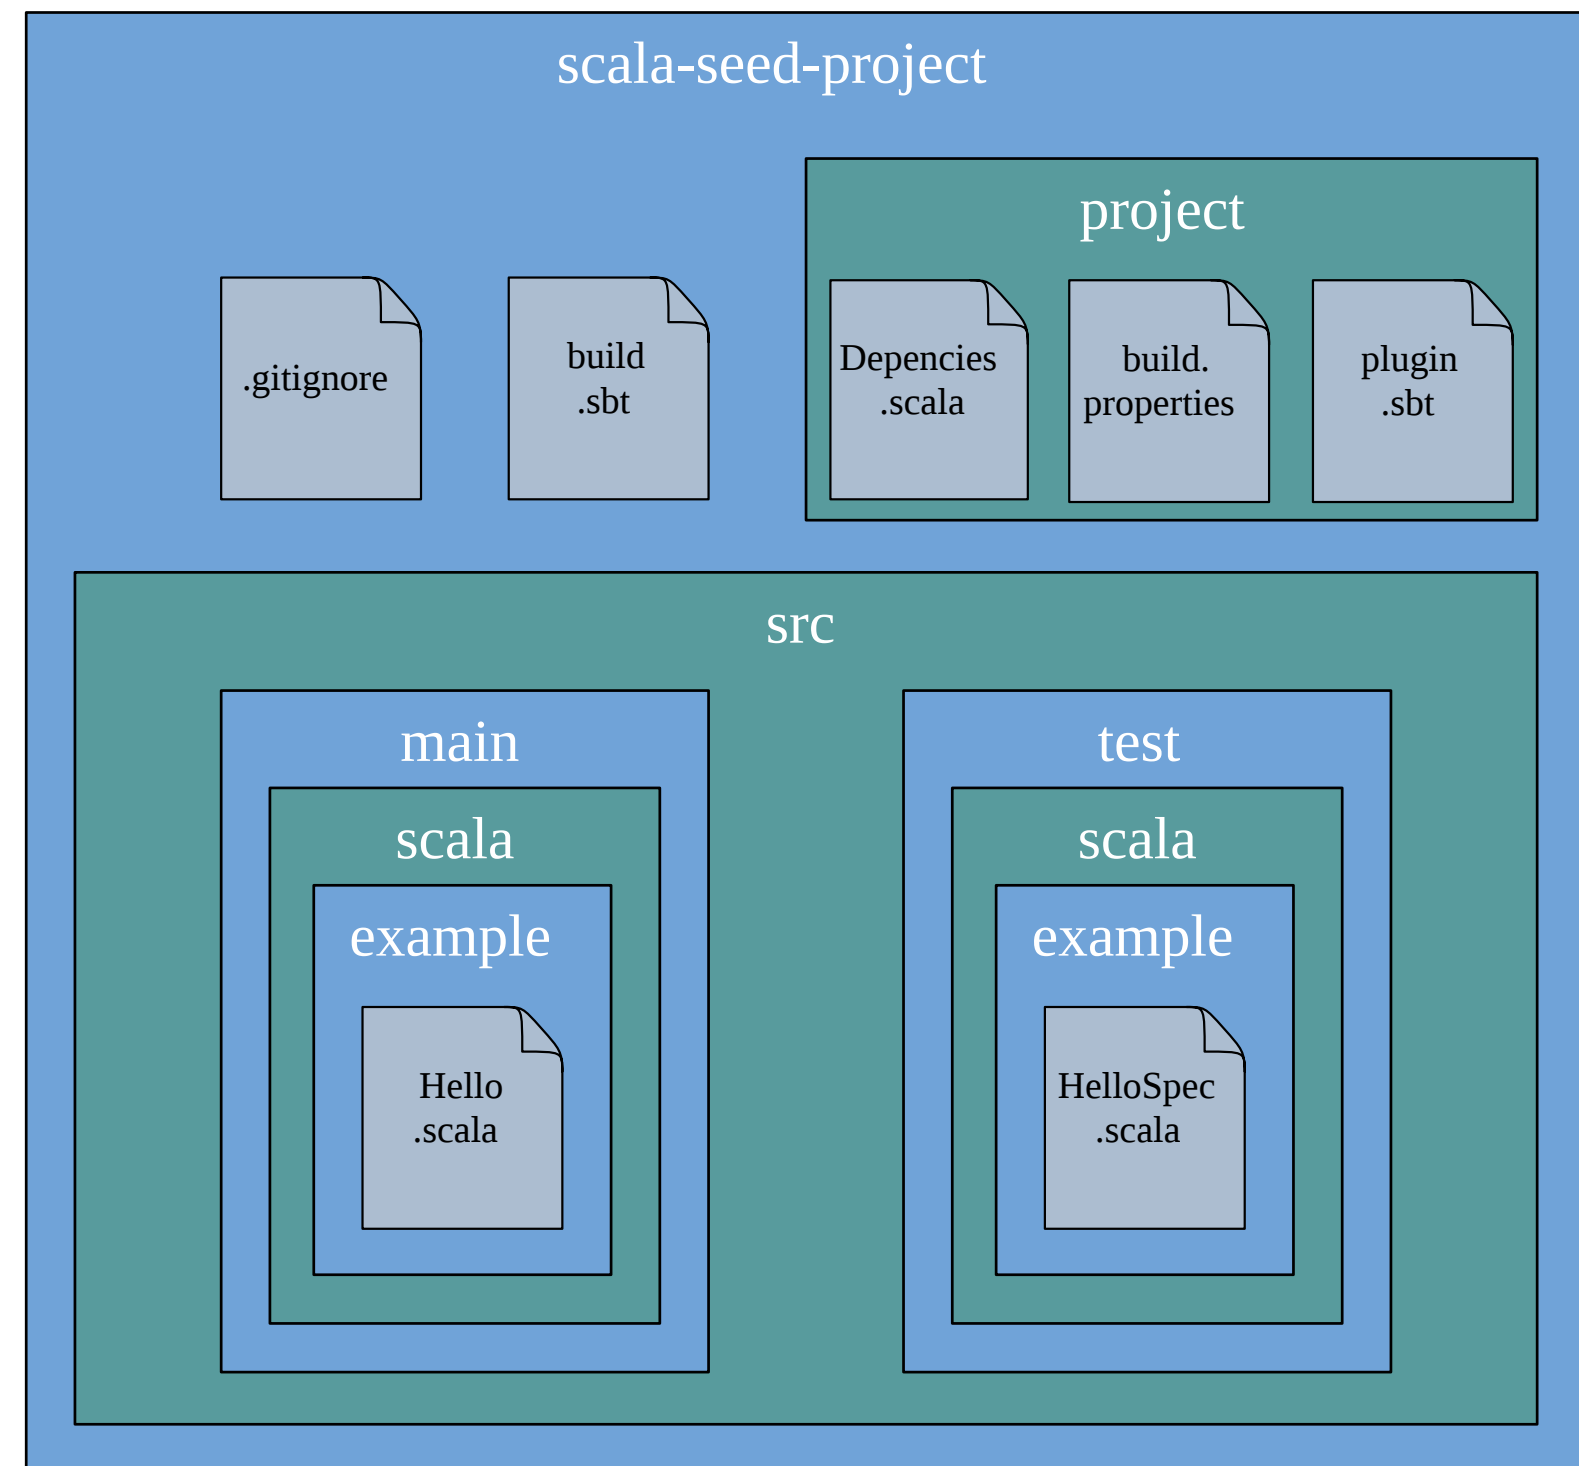

Disk Usage

```
diskUsage(".") =
  diskUsage(".gitignore") +
  diskUsage("build.sbt")  +
  diskUsage("project")    +
  diskUsage("src")
```
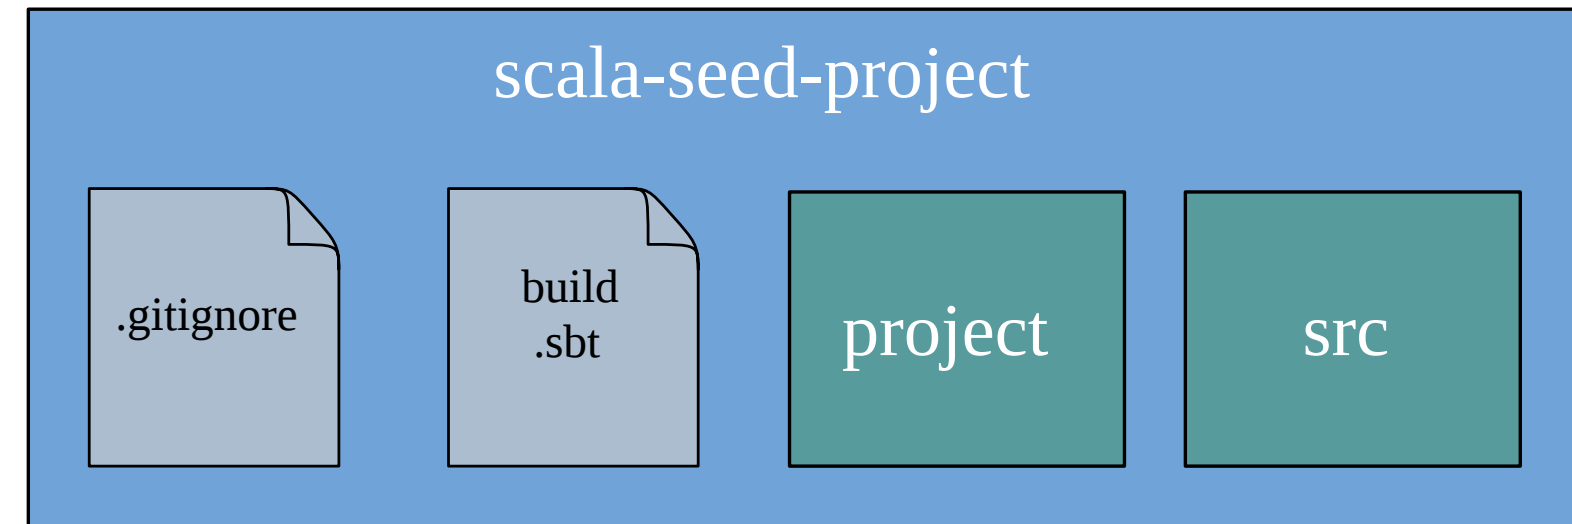

scala-seed-project

.gitignore
build .sbt
project
src
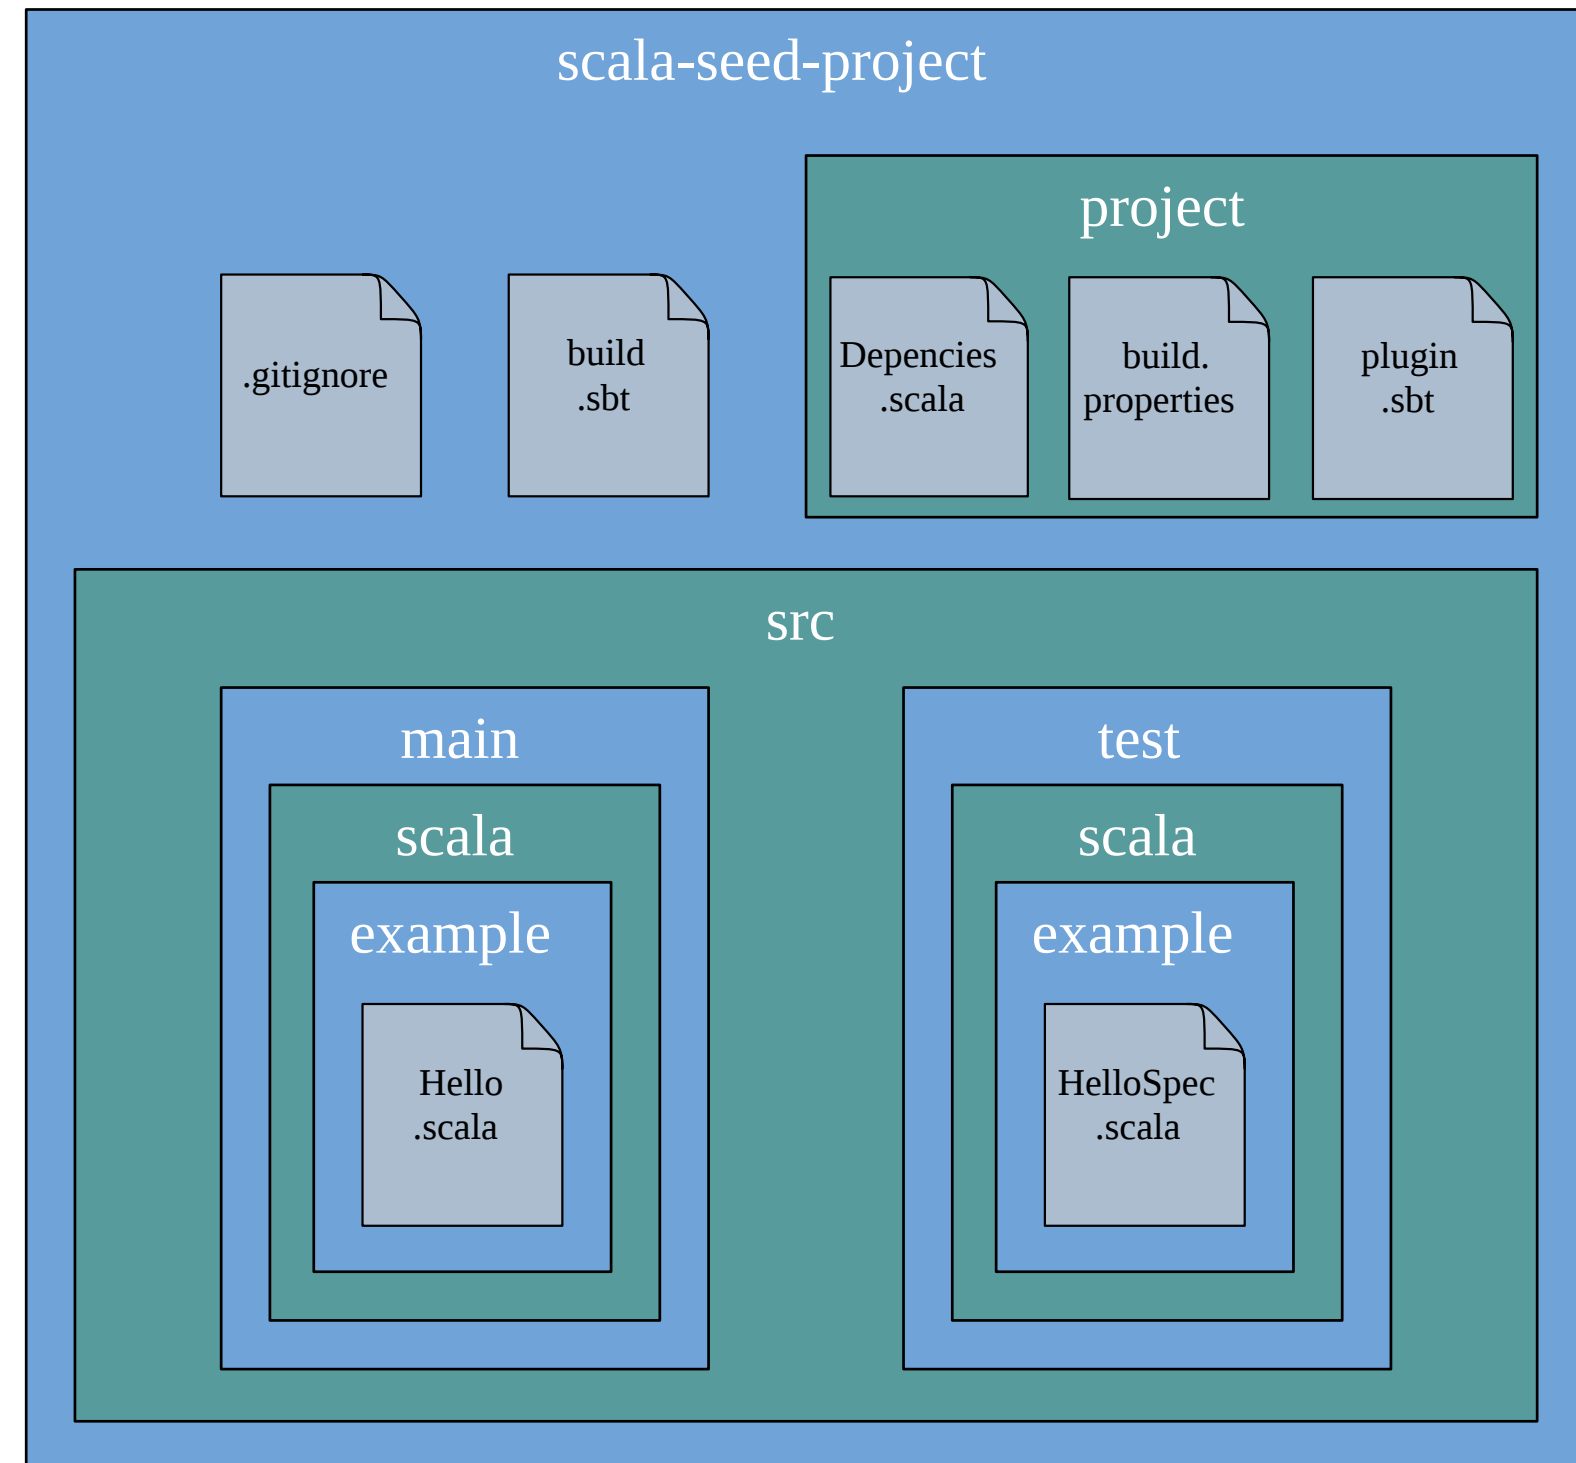

Disk Usage

```
diskUsage(".") =
  4 Kb + // diskUsage(".gitignore")
  4 Kb + // diskUsage("build.sbt")
  diskUsage("project") +
  diskUsage("src")
```
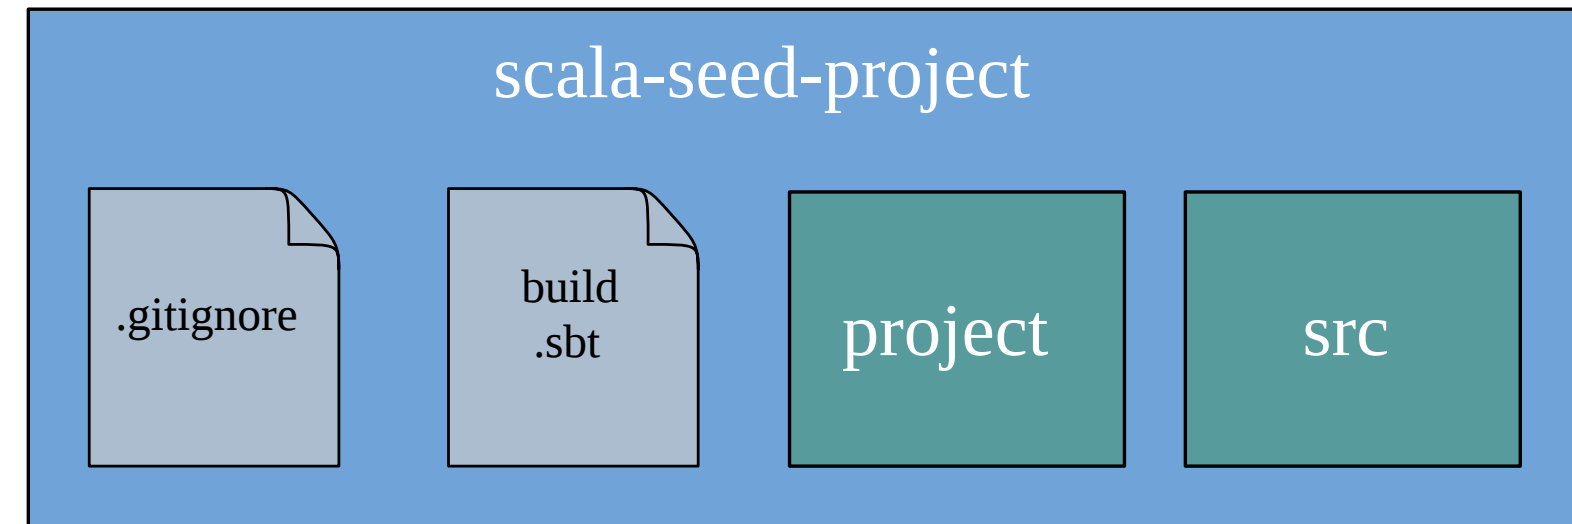

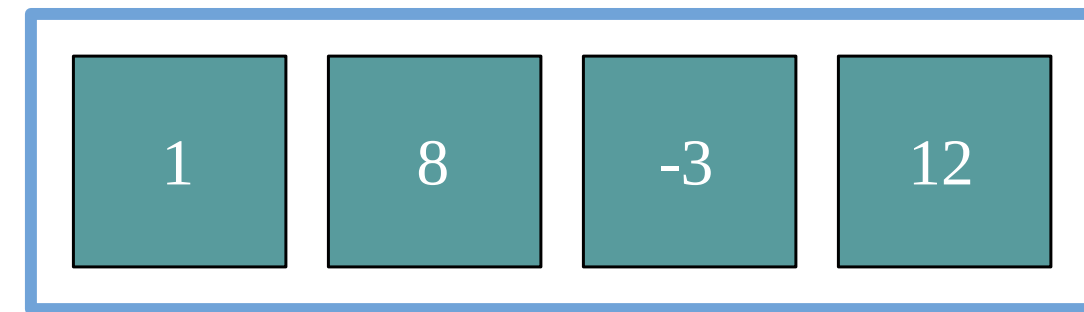

Disk Usage

```
diskUsage("project") =
  diskUsage("project/Dependencies.scala") +
  diskUsage("project/build.properties")   +
  diskUsage("project/plugin.sbt")
```
Disk Usage

```
diskUsage("project") =
  4 Kb + // diskUsage("project/Dependencies.scala
  4 Kb + // diskUsage("project/build.properties")
  4 Kb   // diskUsage("project/plugin.sbt")
```

project
